

Quarkonia Studies in PbPb Collisions by the ATLAS Experiment at LHC

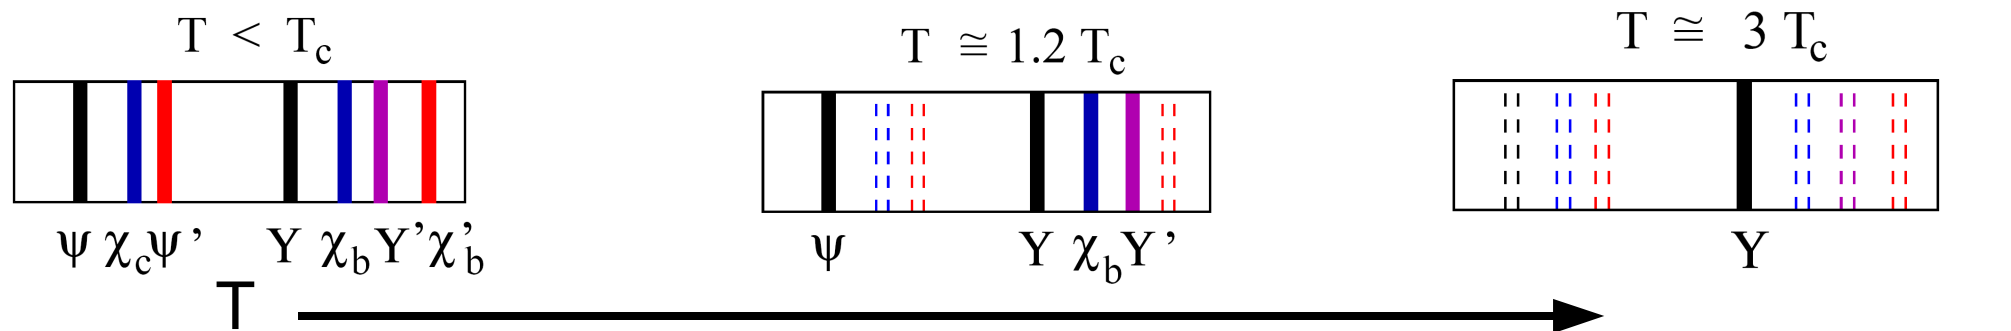

Alexandre Lebedev, Iowa State University
for the ATLAS Collaboration

The Third Workshop of the APS Topical Group in Hadron Physics
April 29 - May 01, 2009, Denver, Colorado

Why Quarkonia?

Quarkonium dissociation due to color screening is considered as a promising signature of QGP formation.

Different quarkonia states are expected to “melt” at different temperatures.

Recent RHIC results point to importance of recombination of quarkonia in the later stages of the collisions.

Also need to consider feed-down from higher resonances

Complicated picture:

It is important to measure simultaneously different quarkonia states in order to understand heavy ion collisions

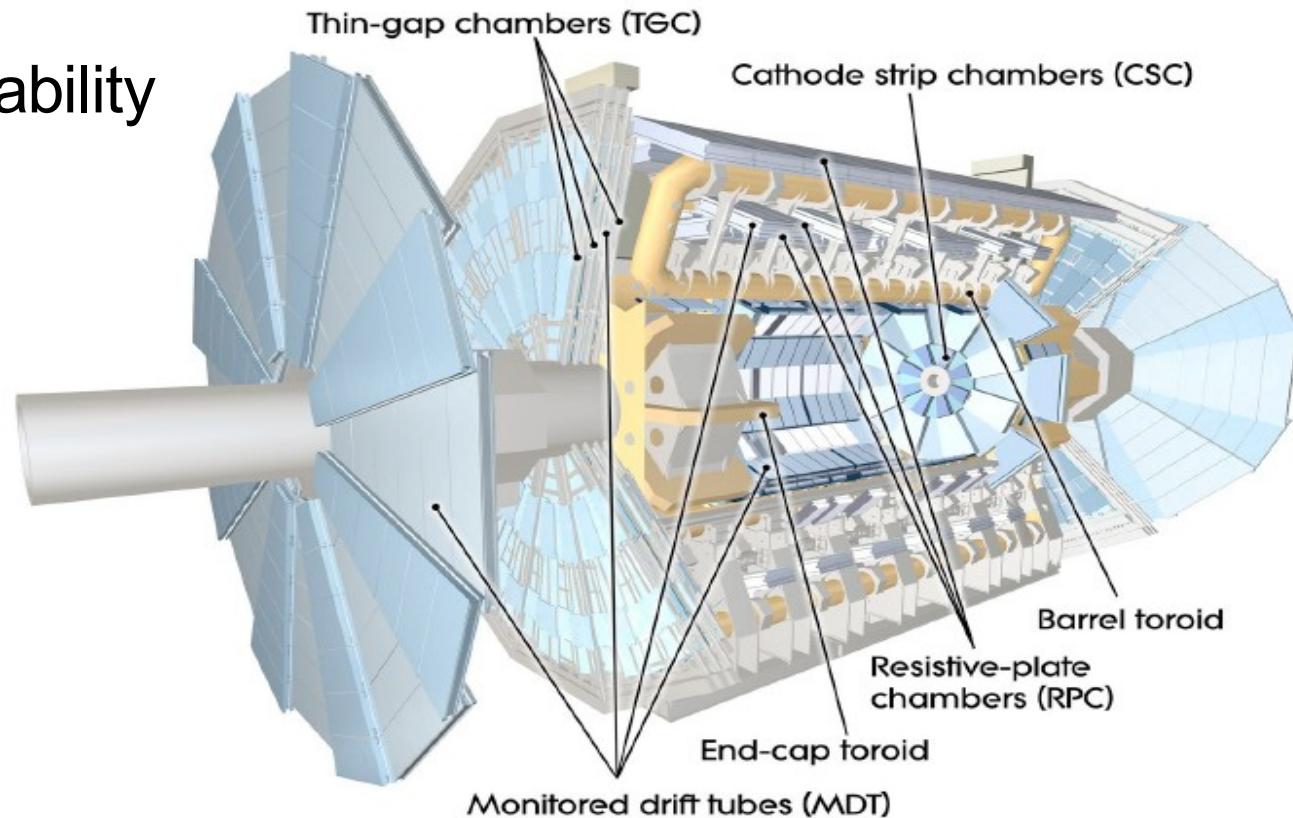

The ATLAS Muon Spectrometer

ATLAS has excellent capability to identify quarkonia in di-muon channel

Toroidal magnetic field created by 3 magnets (barrel and 2 endcaps)

Air-core coils to minimize the multiple scattering

Three layers (stations) in the barrel ($|\eta| < 1$),
Four disks in the endcaps (up to $\eta \sim 2.7$)

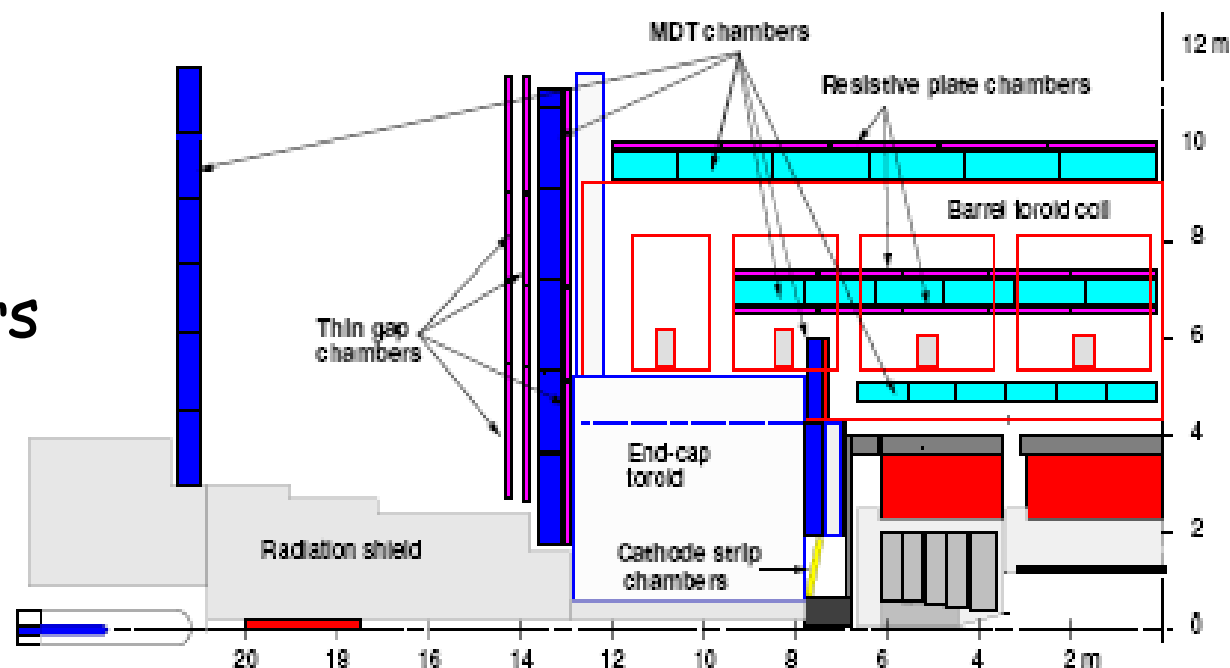

The ATLAS Muon Spectrometer Details

Muon Chambers

Trigger chambers

- Resistive Plate Chambers in barrel (RPC)
- Thin Gap Chambers in the endcaps (TGC)

Momentum measurement chambers

- Monitored Drift Tubes (MDT) in most of the acceptance
- Cathode Strip Chambers (CSC) in most forward region

Provide high P_T resolution $\sim 5\%$ at 10 GeV/c

Coverage: $|\eta| < 2.7$; $P_T > 2.5-3.0$ GeV

Muon Reconstruction in ATLAS

Muon standalone algorithms

- Muon tracks are reconstructed using Muon Spectrometer only

Combined algorithms use information from the Muon Spectrometer and the Inner Tracker (silicon pixels and microstrips)

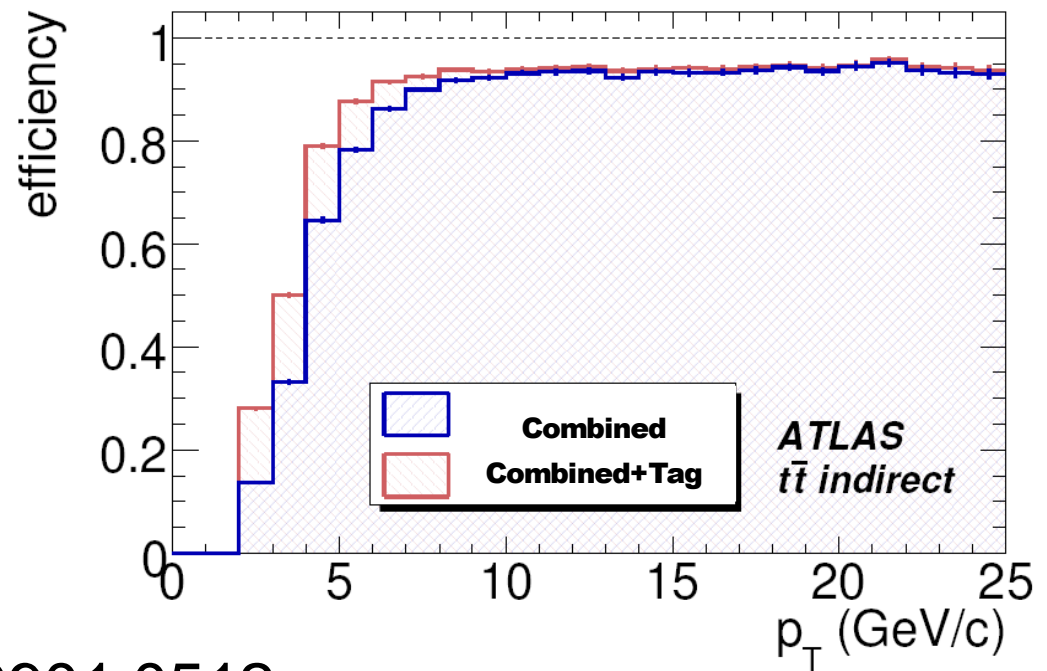

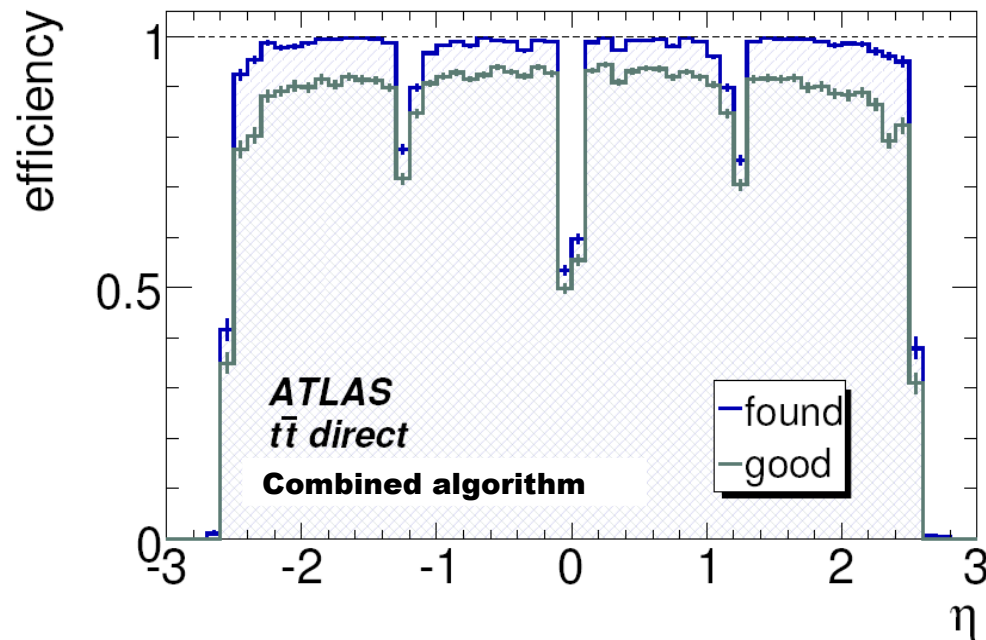

- Muons are found by matching standalone muons to inner tracks and then combining the measurements from two systems.

Tagging algorithms (low P_T)

- Inner tracks are identified as muons if they match unused muon track segments in the first muon station.

Muon Spectrometer Performance in p+p

- Reconstruction efficiency is $>90\%$ for $P_T > 6$ GeV
- Muon momentum resolution $\sim 5\%$ at 10 GeV
- Wide η coverage.

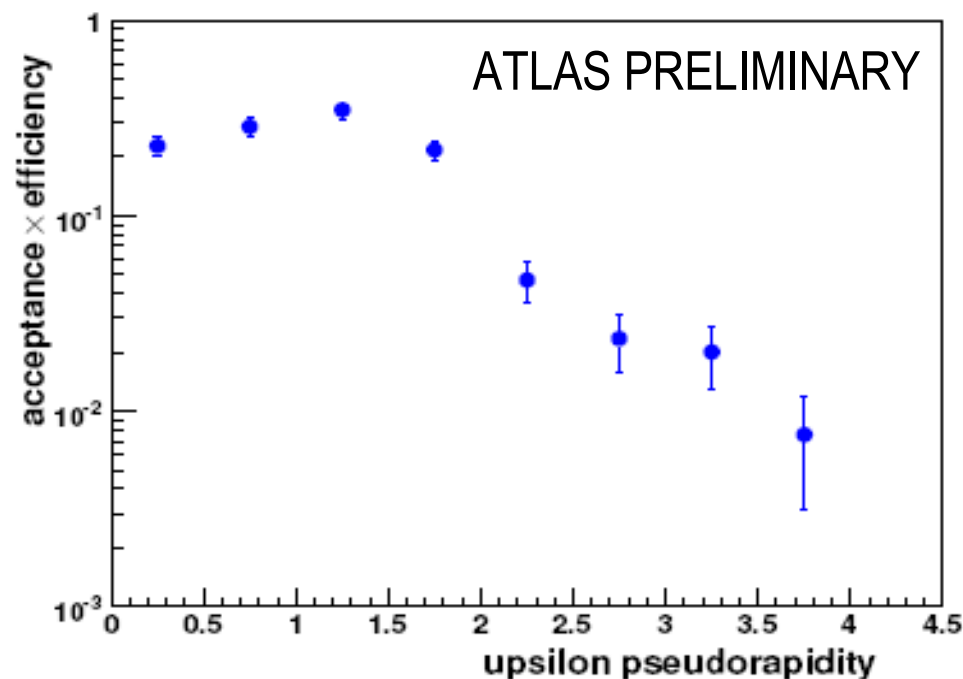

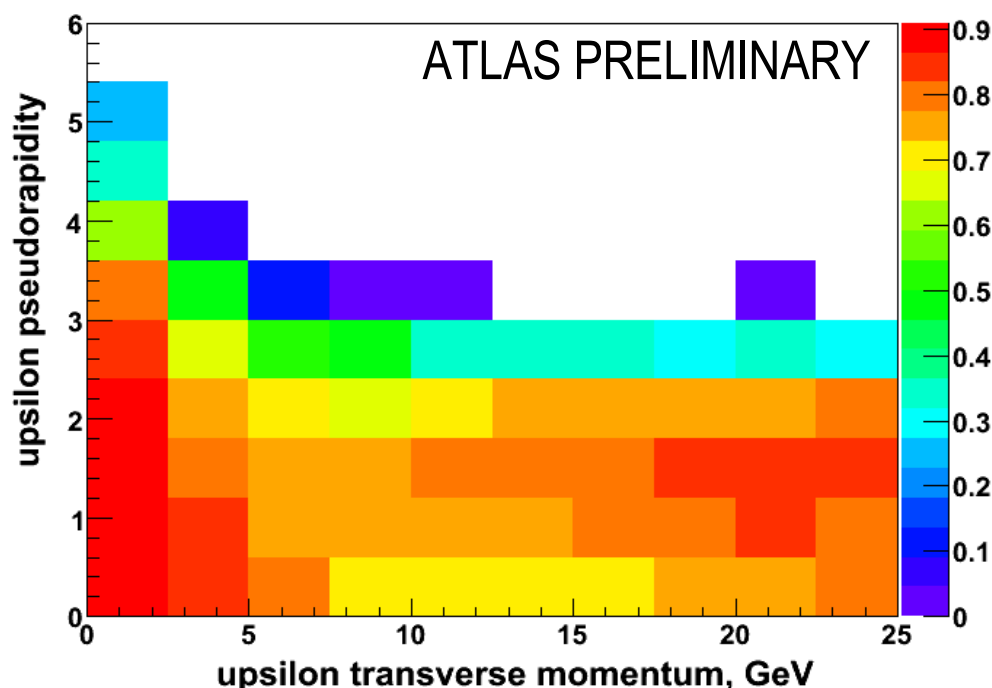

arXiv:0901.0512

Upsilons in Pb+Pb Events

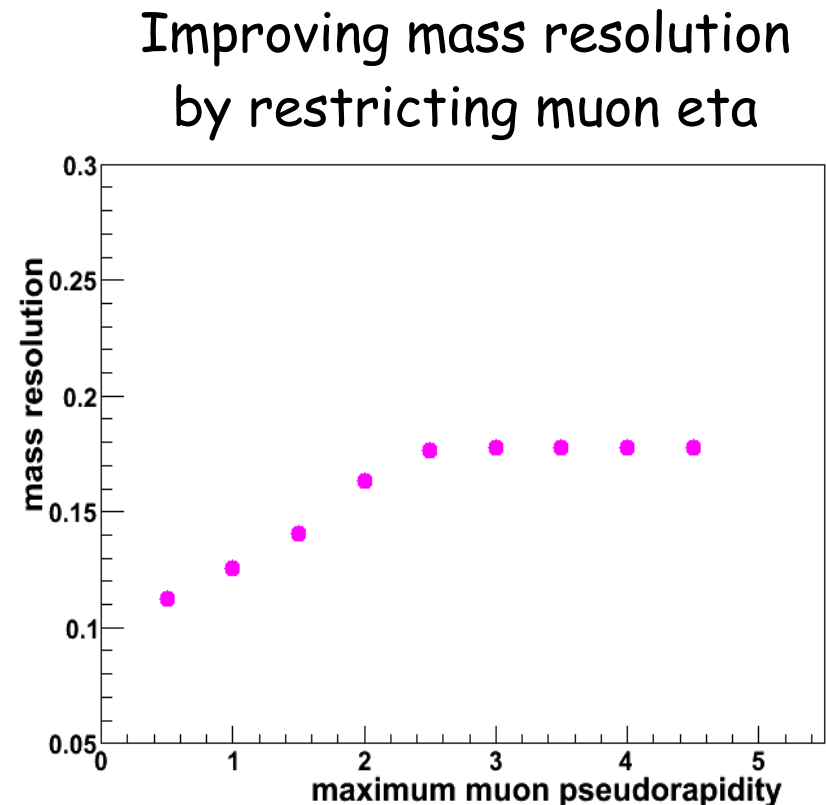

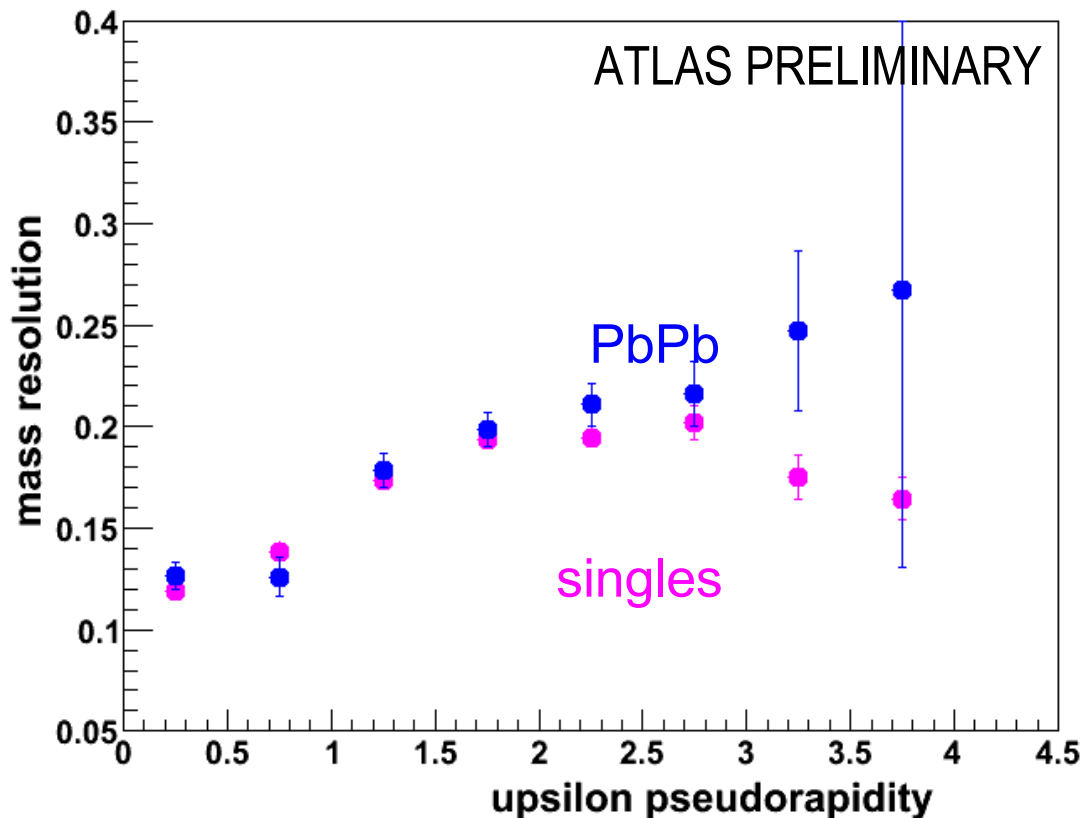

ATLAS ability to measure quarkonia in Pb+Pb collisions at 5.5 TEV was studied by merging single quarkonia to minimum bias Hijing Pb+Pb events and running full reconstruction chain.

- singles had flat distribution in P_T and η , weights from PYTHIA were used to fill histograms.

Upsilon Mass Resolution (Pb+Pb)

- Integrated (over P_T and η) mass resolution is ~ 190 MeV
- Mass resolution for $|\eta_Y| < 1 = 120$ MeV
- Best mass resolution (both muons in barrel) = 112 MeV
- Mass resolution is unaffected by high multiplicity

Background and Yields (1/2)

Assume that both high p_T muons and Y scale with number of binary collisions. Then background will scale as a square of signal, and S/\sqrt{B} ratio will be the same for pp and $PbPb$.

Sources of background:

a) open charm and beauty

- use pythia to get muons from charm/beauty

b) hadron decays (mostly π & K) and hadron punch-through

- generate single pions and kaons, run full simulation, plot reconstructed muon spectrum

Add Upsilons to this mix.

Scale everything with number of binary collisions:

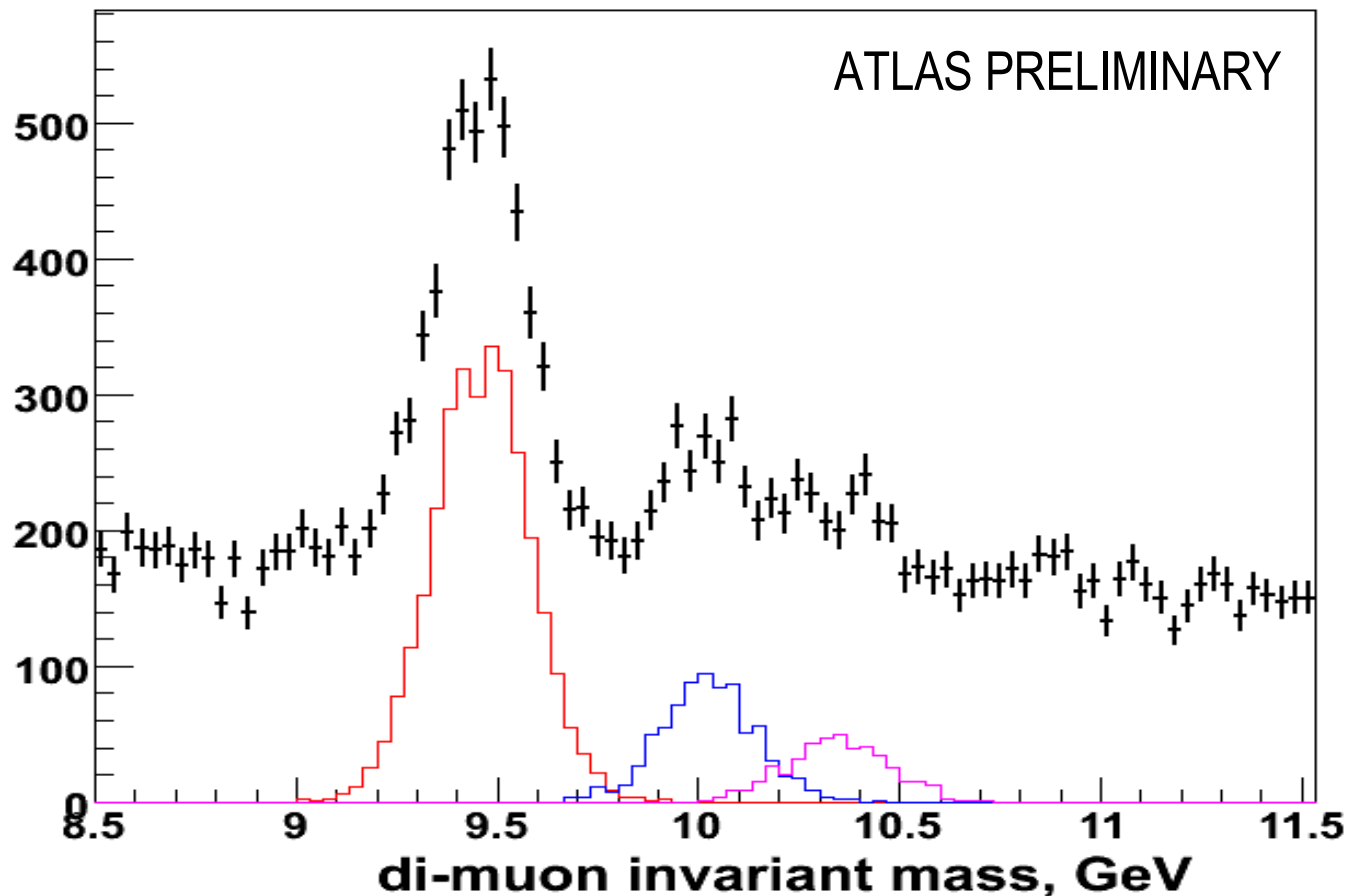

400 (MB); 1670 (central) (*David d'Enterria, nucl-ex/0302016*):

Run MC simulation and produce di-muon invariant mass spectra.

Background and Yields (2/2)

Plot for one month of running at nominal luminosity with 50% LHC+ATLAS efficiency, equivalent to integrated luminosity of 0.5nb^{-1}

Acceptance and efficiency corrected, no trigger efficiency. Barrel only.

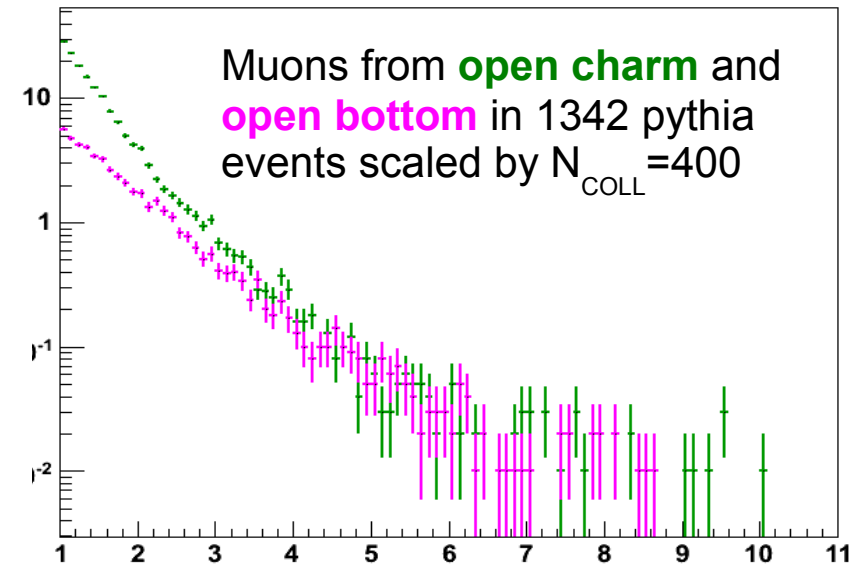

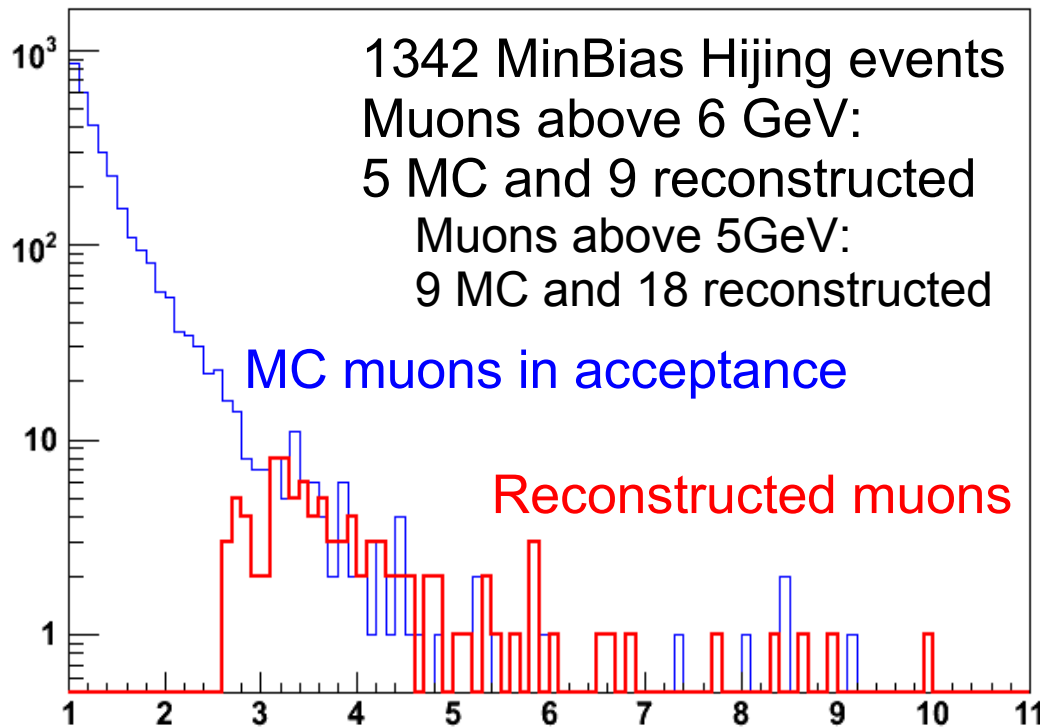

Upsilon Triggering Issues

We may have to use Level-1 trigger to scale down from several thousand Hz collision rate to 50 Hz (or less) to tape.

Sources of high P_T muons:

- hadron decays and punch-throughs
- open charm and bottom

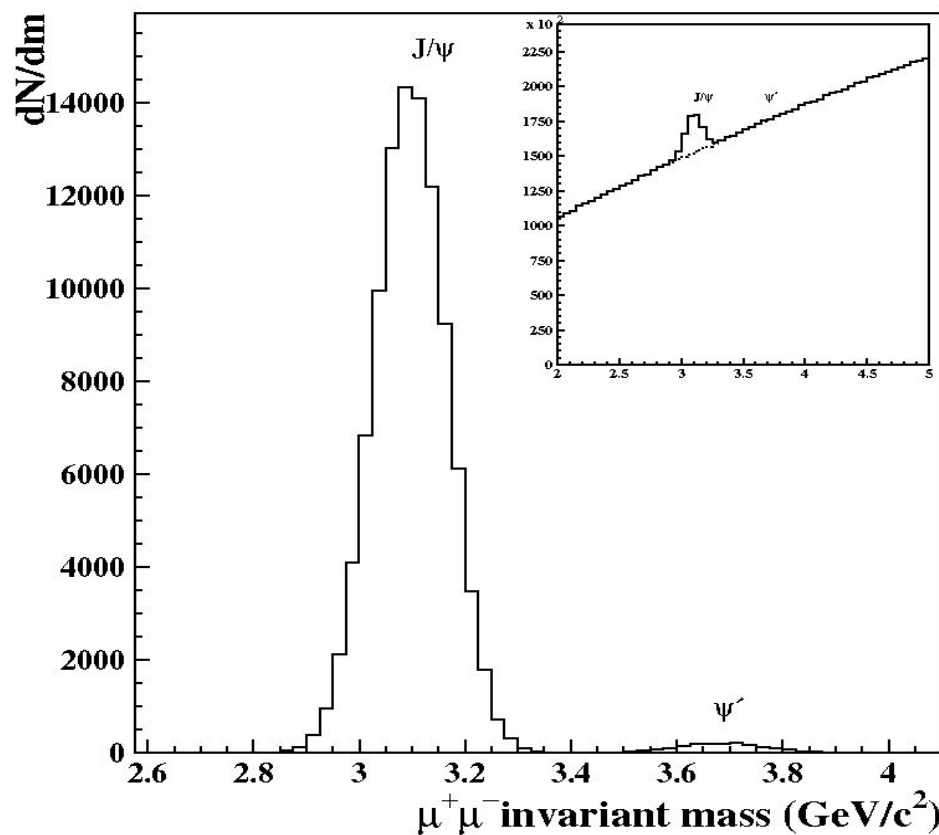

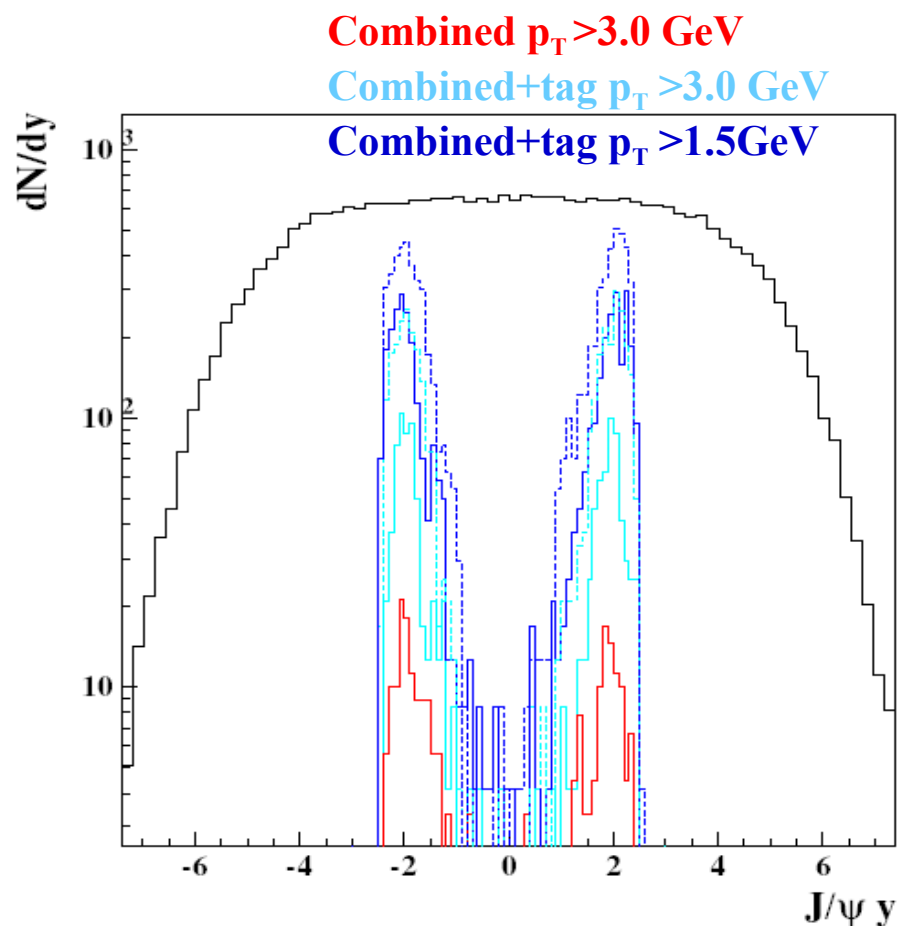

Upsilon triggering efficiency:
L1_MU4: 79%
L1_MU6: 60%
L1_MU10: 26%
(from Upsilon's in PYTHIA)

J/ψ Reconstruction in Pb+Pb Events

Main problem: low acceptance due to minimum muon $P_T \sim 2.5\text{-}3.0\text{ GeV}$

Two methods considered:

- both muons fully reconstructed
- “tagging method” for one muon (*allows muon reconstruction down to 1.5 GeV*).

Mass resolution 68 MeV; tagging method

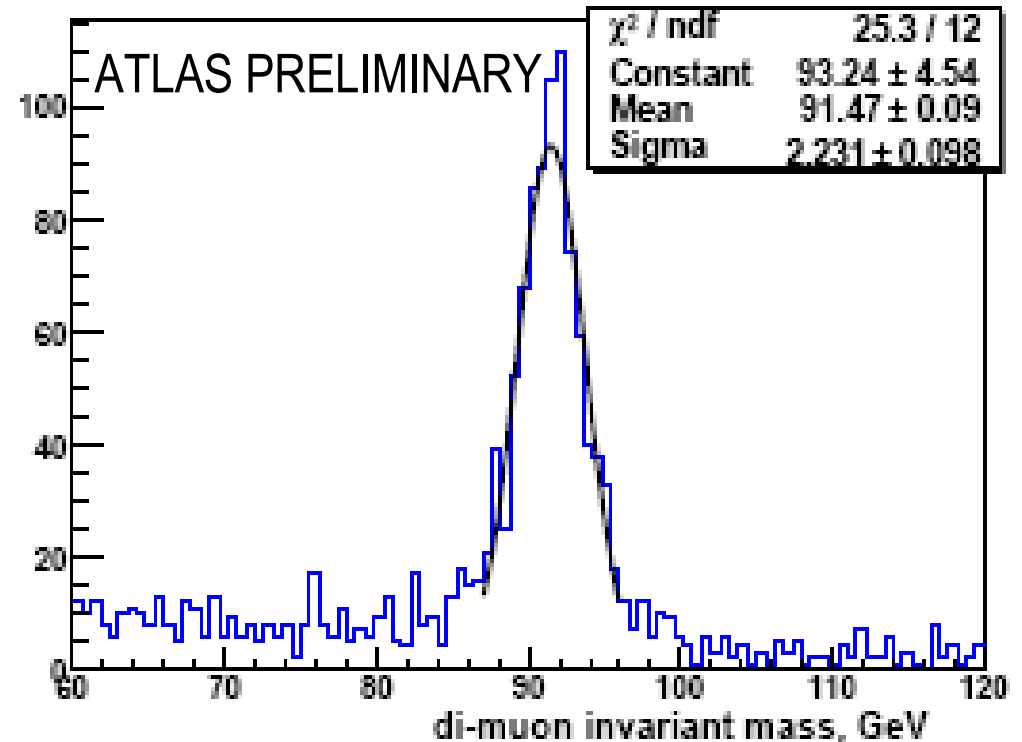

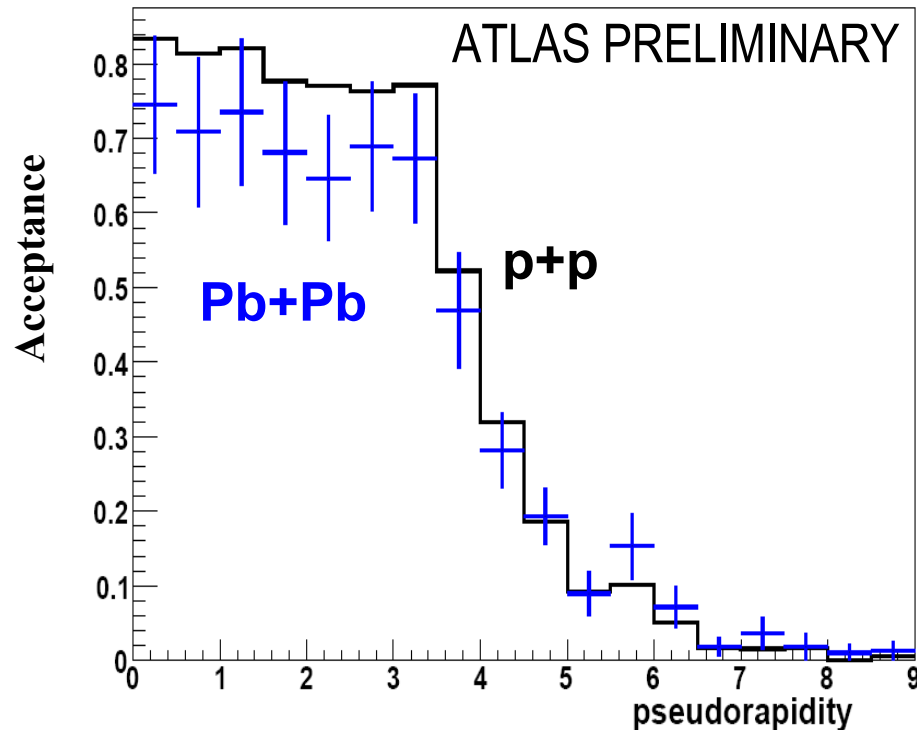

Summary of Quarkonia Performance

	J/ψ	Y	Y (μ in barrel)
Acceptance x efficiency	0.53%	12.5%	4.7%
Mass resolution (MeV)	68	190	112
Signal/Background	3:20	3:10	4:10
Rate/month	130k	19k	7k

Rates calculated for one month of running at nominal luminosity with 50% LHC+ATLAS efficiency, equivalent to integrated luminosity of 0.5nb^{-1}

Z⁰ Bosons

- No pA collisions at LHC
- Use Z to determine “cold nuclear matter” effects
 - Z production in p+p can be accurately calculated in pQCD,
 - Measuring Z in Pb+Pb will provide information about PDF modification

Acceptance x efficiency ~60%

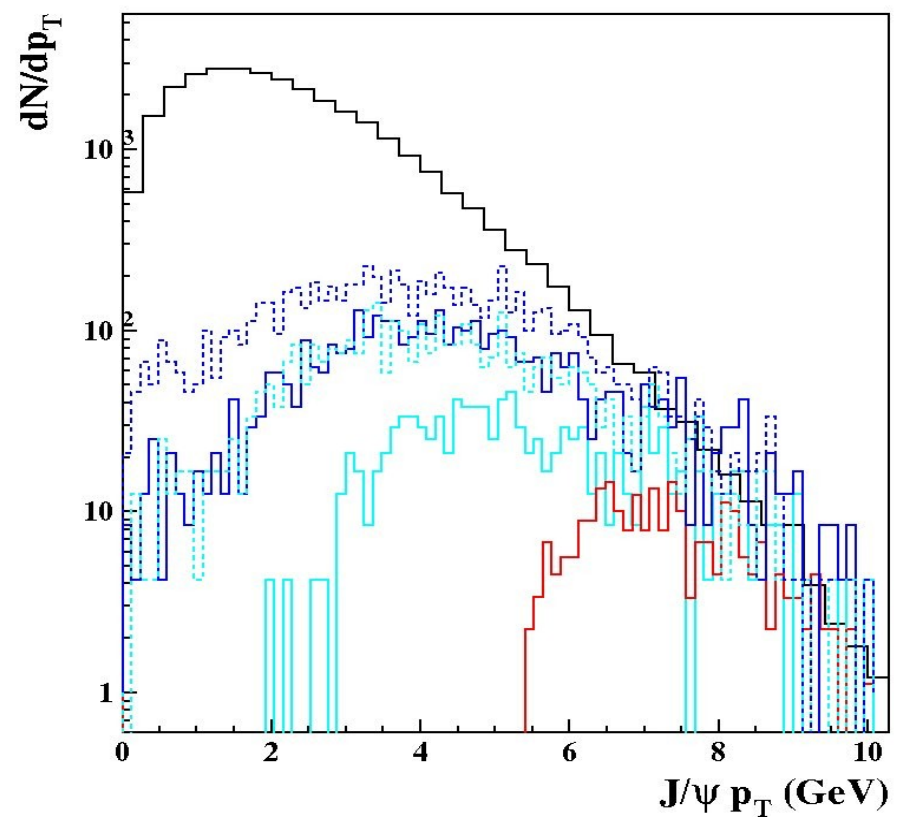

Mass resolution ~2.2 GeV (almost unchanged in Pb+Pb)

Rate ~8k per month

Conclusions and Outlook

- ATLAS has excellent capability to measure quarkonia in heavy ion collisions at LHC
- Quarkonia mass resolution is almost unaffected by high multiplicity, and good enough to separate 3 Y states
- Should be able to see Y and J/ψ peaks in few weeks of running
- Feasibility studies of χ_c measurement and quarkonia in e^+e^- channel are underway

Why Quarkonia?

Quarkonium dissociation due to color screening is considered as a promising signature of QGP formation.

- Different quarkonia states are expected to “melt” at different temperatures.

Recent RHIC results point to importance of recombination of quarkonia in the later stages of the collisions.

- Also need to consider feed-down from higher resonances

Complicated picture:

- It is important to measure simultaneously different quarkonia states in order to understand heavy ion collisions

In this talk we study possibility to measure charmonium (J/ψ) and bottonium (Y) states via di-muon channel in PbPb collisions by the ATLAS experiment at LHC.

Background and yields (1/3)

Total pp cross-section at 5.5 TeV: $\sim 100\text{mb}$

$b\bar{b}$ cross-section at 5.5 TeV: $\sim 100\mu\text{b}$

Y cross-section: $\sim 100\text{nb}$

- Upsilon cross-section in pp collisions was studied using pythia:

<http://dprice.web.cern.ch/dprice/work/oniumvalidation-jun06.pdf>

- 34nb with default trigger cuts, $\sim 150\text{nb}$ with relaxed trigger cuts.

One Upsilon reconstructed in $\sim 1\text{M}$ pp events

PbPb expected luminosity is $4 \cdot 10^{26} \text{ cm}^{-2}\text{s}^{-1}$ (Letter of Intent)

- Interaction rate several thousand Hz

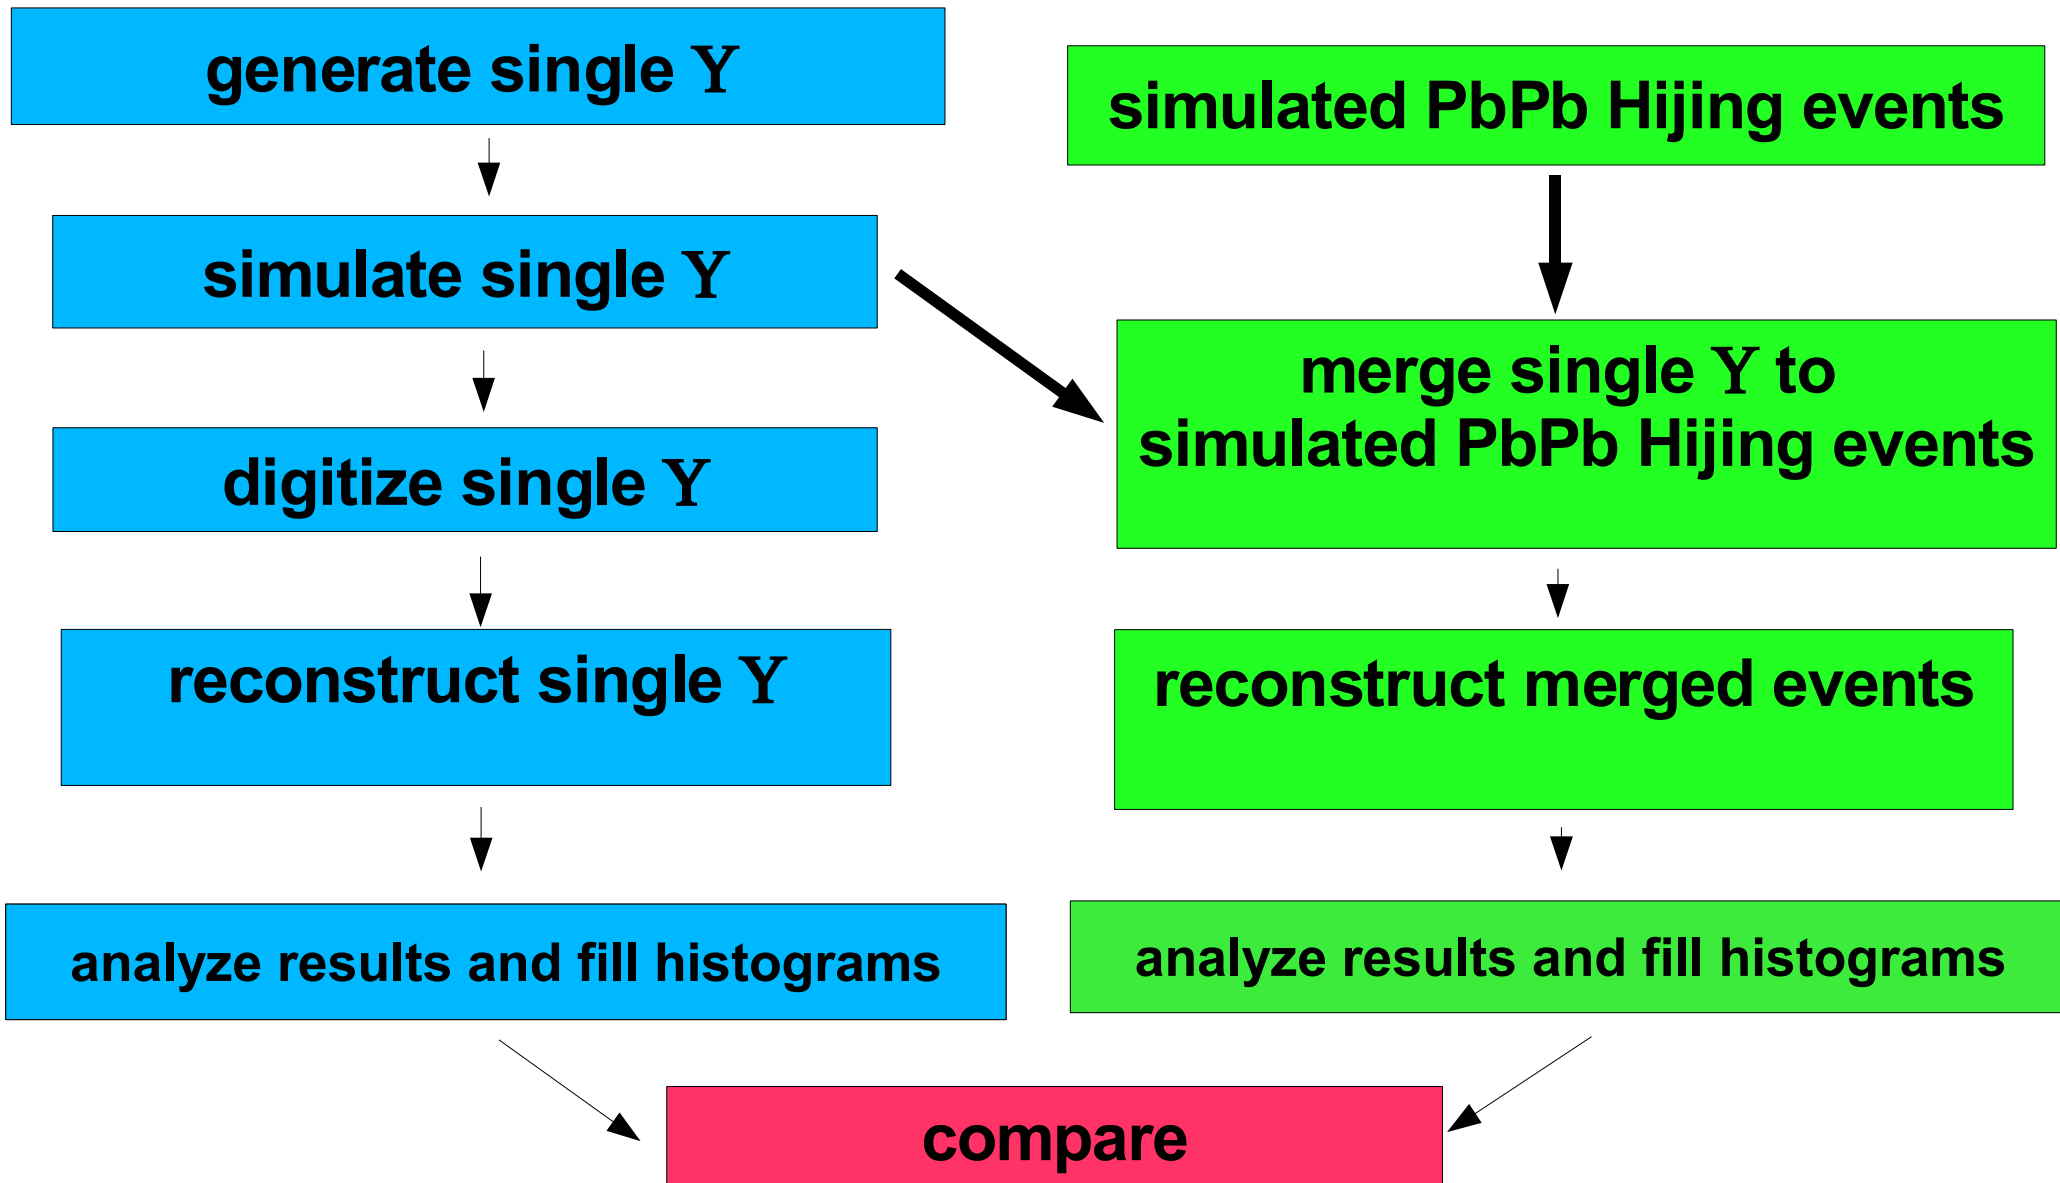

from Glauber calculation (*David d'Enterria, nucl-ex/0302016*):

- Total PbPb cross-section: 7.7b
- Number of binary collisions: 400 (MB); 1670 (central)

Assume that both high p_T muons and Y scale with number of binary collisions. Then background will scale as a square of signal, and S/\sqrt{B} ratio will be the same for pp and PbPb.

Heavy Ion Simulation Study

Υ with flat P_T and η distributions, weighted with Pythia distributions.

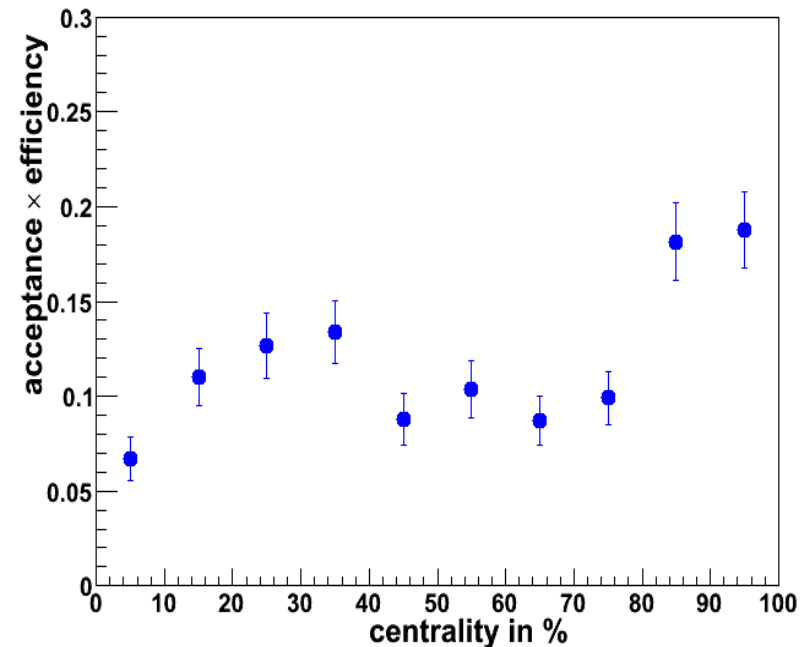

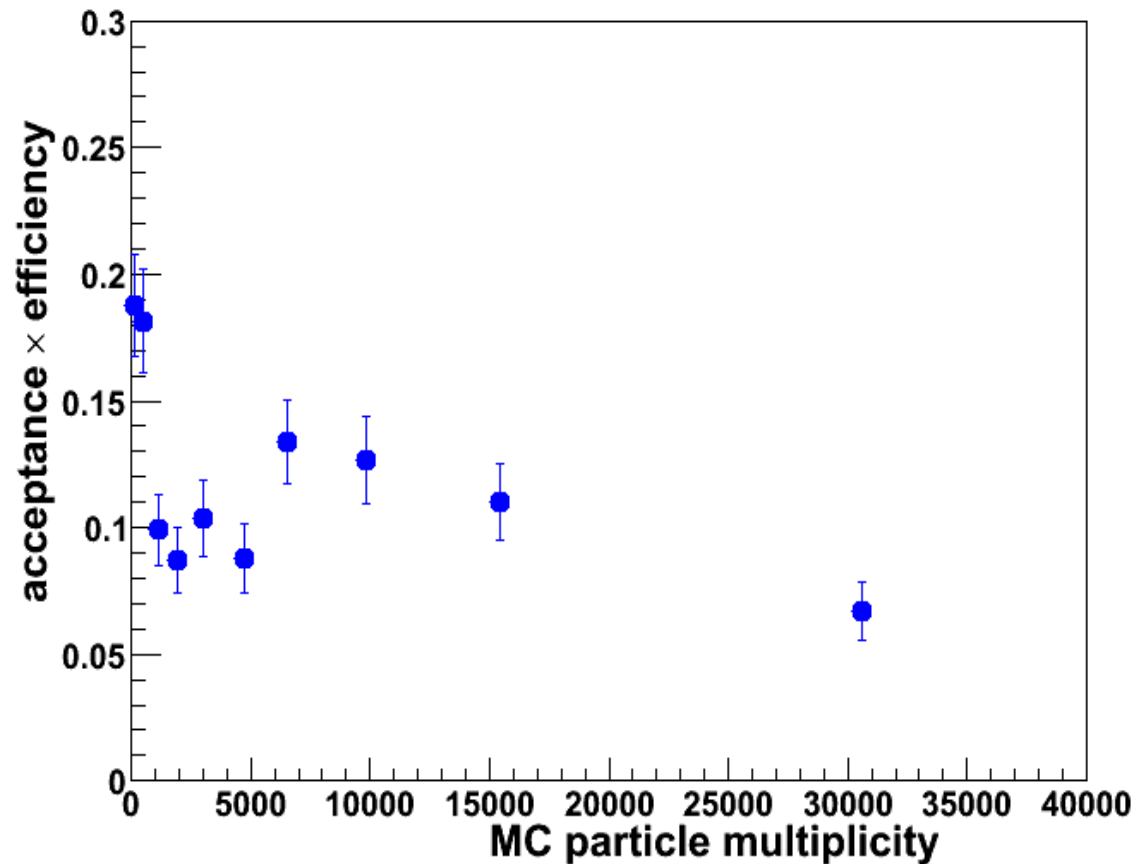

Conclusions and outlook

- Reconstruction efficiency is reasonably good even in most central PbPb events
- Mass resolution is almost unaffected in PbPb collisions
- Mass resolution is good enough to separate different Y states at least in the barrel region
- We should be able to see Y and J/ψ peaks in a few weeks of running
- Quarkonium study in e^+e^- channel is underway
- χ_c study is underway

Reconstruction efficiency vs centrality

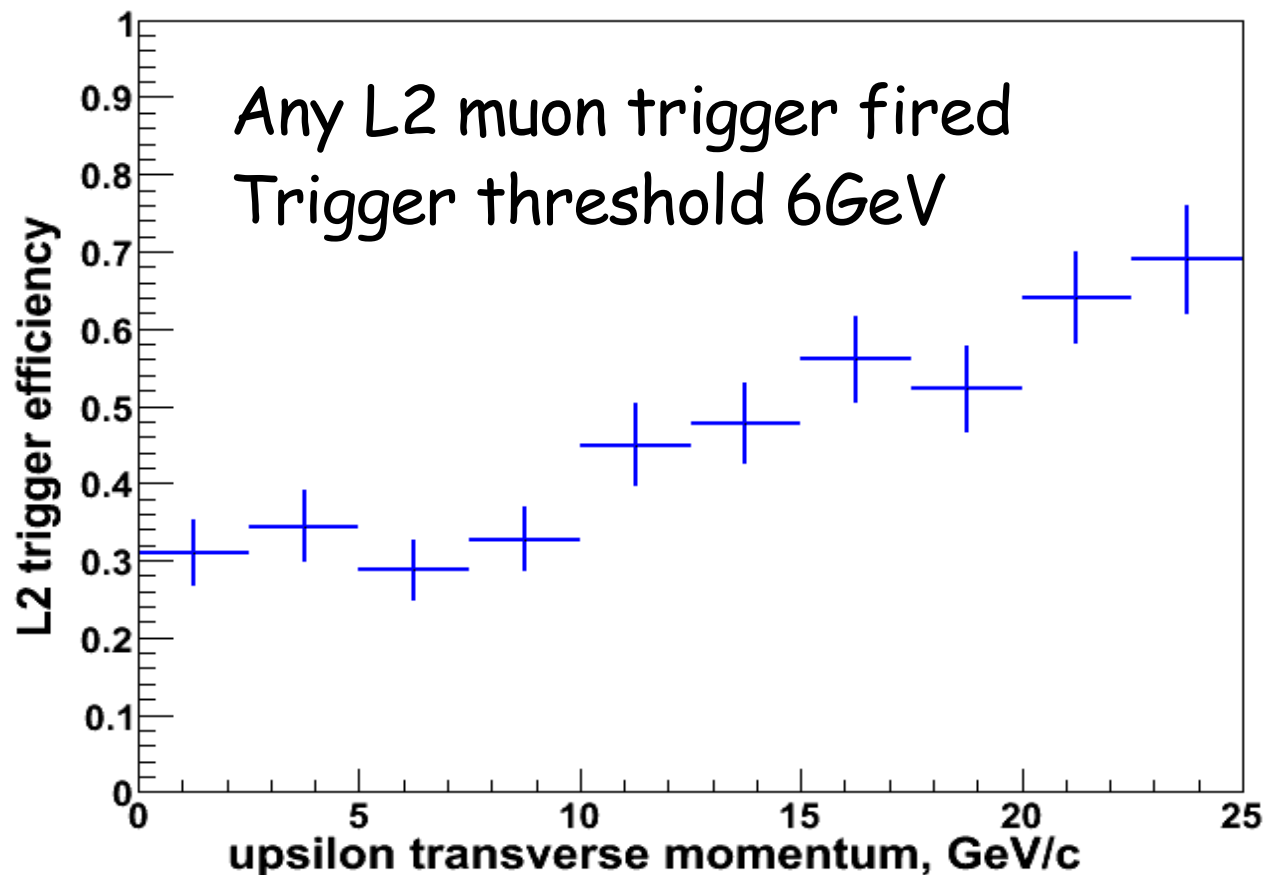

- Integrated (over P_T and η) acceptance times efficiency is 0.12
- Factor of ~ 2 loss in most central collisions

Triggering on Upsilons

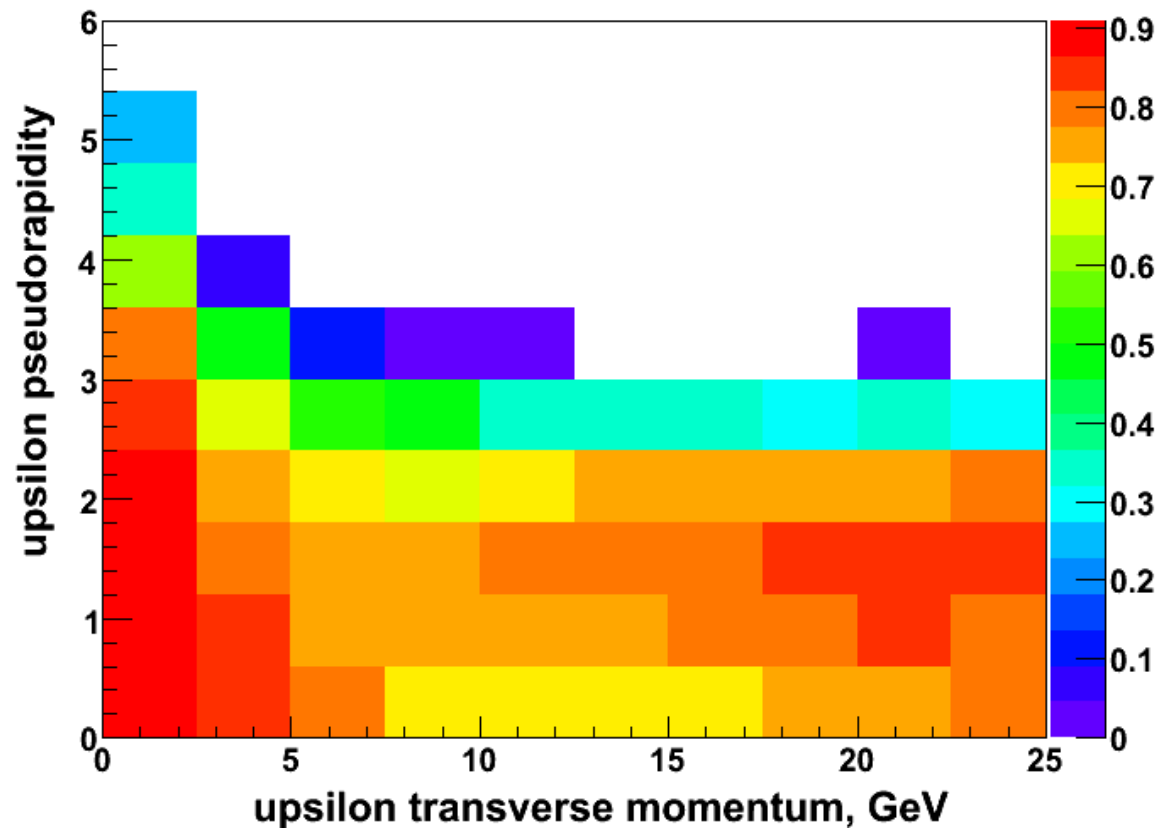

efficiency = (Y reconstructed & muon trigger fired)/(Y reconstructed)

No fakes in ~250 PbPb Min. Bias Hijing events (without Y merging)

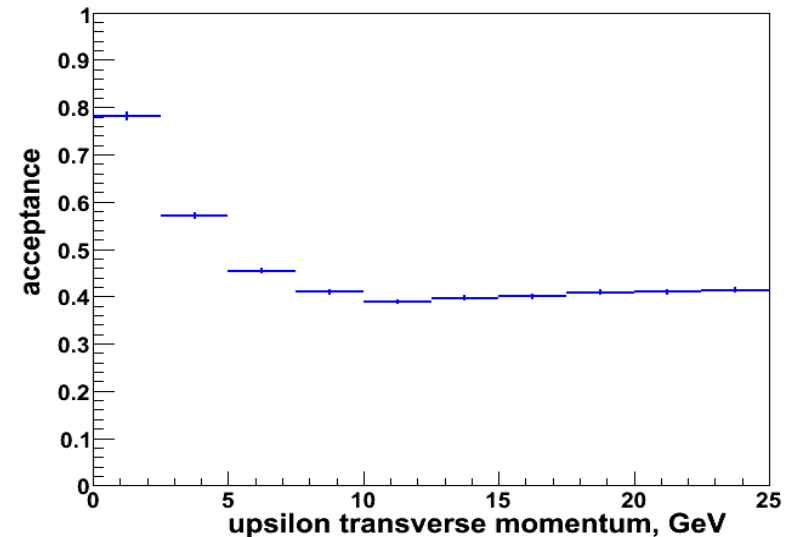

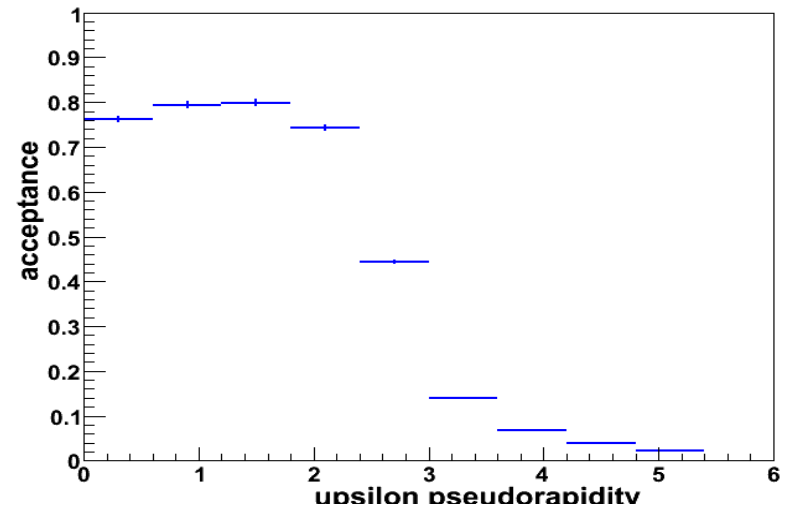

Y acceptance (singles)

Y was considered to be in acceptance if both muons produced hits in muon detector.

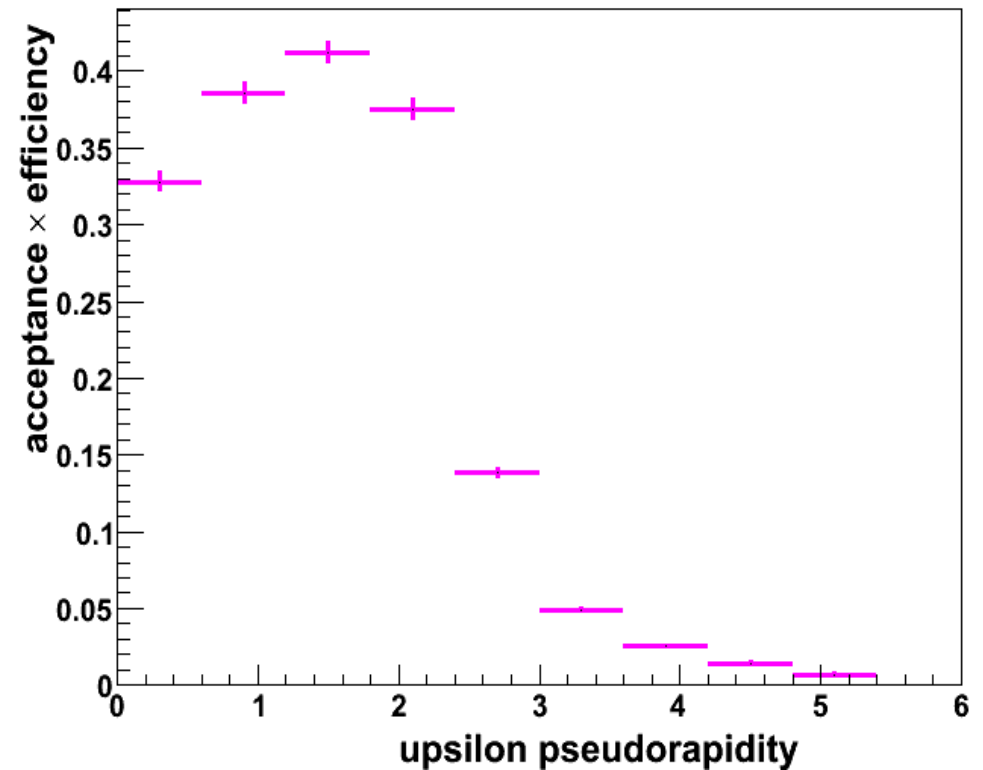

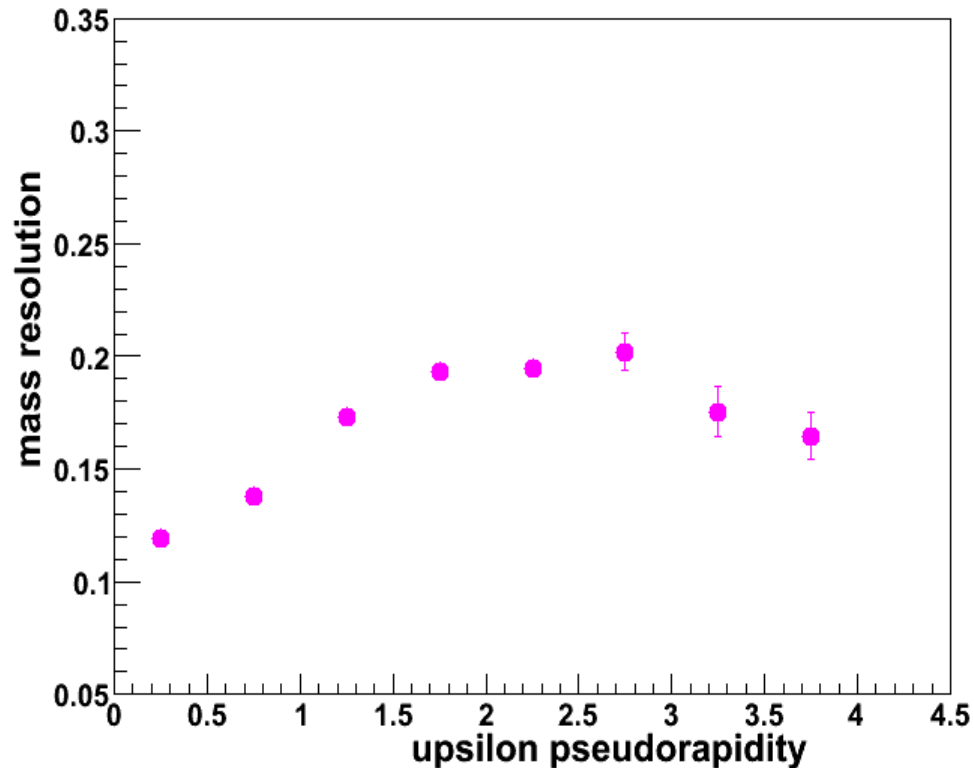

Projections are done with P_T and η distributions from pythia.

Single Υ (baseline for PbPb)

Integrated (over P_T and η) mass resolution is 177 MeV.

Integrated acceptance times efficiency is ~ 0.19

Muon triggers

ATLAS Trigger system:

- Level 1 (L1) – configurable hardware

Higher Level Triggers (HLT):

- Level 2 (L2) – software, relies on input from L1
- Event Filter (EF) – off-line algorithms and data model

In PbPb interaction rate is expected to be $\sim 3\text{kHz}$

Probably no need for L1 trigger for data taking

But need HLT for analysis

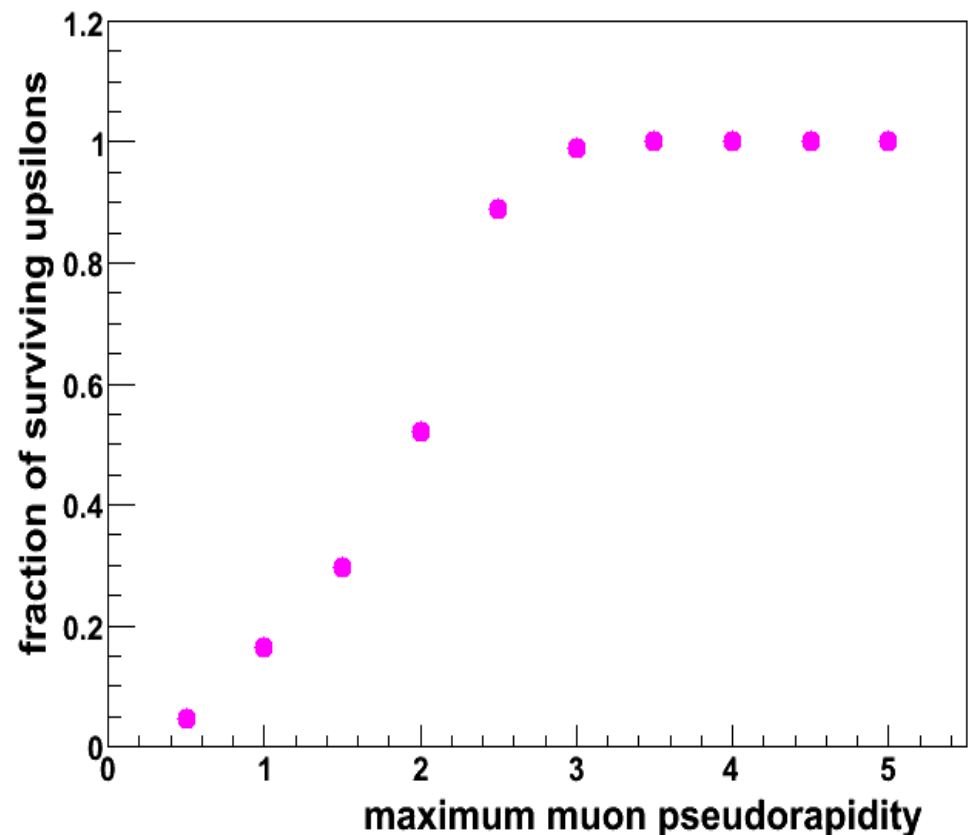

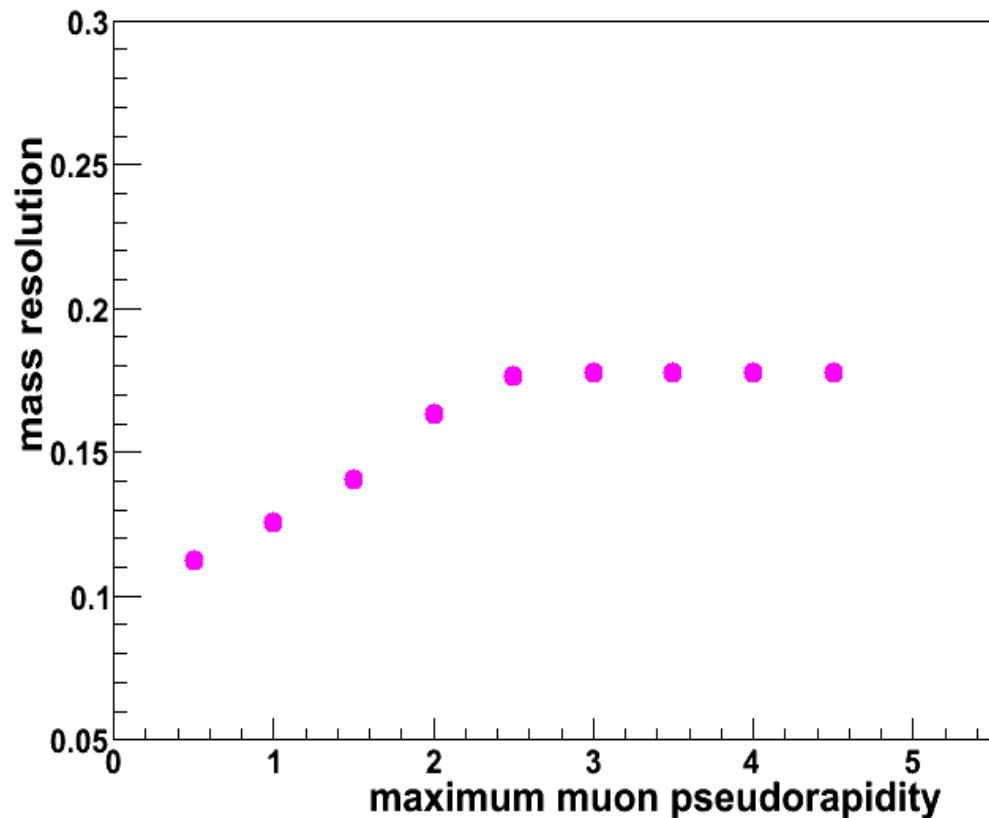

*We studied L2 trigger efficiency using merged
Upsilon/PbPb events, and fake rate using
pure PbPb Hijing events.*

Improving mass resolution

Restrict muon pseudorapidity - but loose statistics.

Best mass resolution ~ 111 MeV ($\sim 10\%$ improvement)

Tighter reconstruction cuts can slightly improve this number
- still further loss in statistics

Measuring quarkonia in ATLAS

Quarkonia are measured in di-muon decay channel. ATLAS has excellent muon detection capabilities for $|\eta| < 2.6$ and $P_T > \sim 2.5$ GeV/c

MDT: Monitored drift tubes (barrel and endcaps)

CSC: Cathode strip chambers (endcaps)

RPC: Resistive Plates Chambers (barrel trigger)

TGP: Thin Gap Chambers (endcaps and barrel trigger)
